ABSTRACT

Objective: To investigate whether dementia incidence has changed over the last 2 decades

Methods: We compared d
years from the Rotterdam
1990 (n = 5,727), the se
and followed for at maxin
the 2 subcohorts in total
compared mortality rates
Finally, we compared brai
who underwent brain ima

Results: In the 1990 subc
the 2000 subcohort (8,384 person-years), 49 persons. Age-adjusted dementia incidence rates were consistently, yet nonsignificantly, lower in the 2000 subcohort in all strata, reaching borderline significance in the overall analysis (incidence rate ratio 0.75, 95% confidence interval [CI] 0.56–1.02). Mortality rates were also lower in the 2000 subcohort (rate ratio 0.63, 95% CI 0.52–0.77). The prevalence of hypertension and obesity significantly increased between 1990 and 2000. This was paralleled by a strong increase in use of antithrombotics and lipid-lowering drugs. Participants in 2005–2006 had larger total brain volumes ($p < 0.001$) and less cerebral small vessel disease (although nonsignificant in men) than participants in 1995–1996.

Conclusions: Although the differences in dementia incidence were nonsignificant, our study suggests that dementia incidence has decreased between 1990 and 2005. *Neurology*® 2012;78: 1456-1463

Table 2 Age-adjusted dementia incidence rates and incidence rate ratios of the 2000 vs the 1990 subcohort[a]

Age stratum, y	Total	Men	Women
All			
Incidence rate 1990	6.56	6.25	6.78
Incidence rate 2000	4.92	4.48	5.20
IRR (95% CI)	0.75 (0.56-1.02)	0.72 (0.44-1.16)	0.77 (0.52-1.14)

Dementia incidence in 2000 vs 1990 declined

Larger brain volume in 2000 cohort

Lower WMH burden in 2000 cohort

Vascular Dementia: imaging criteria

Vascular dementia caused by vascular pathology

DSM V and NINDS-AIREN criteria for diagnosis

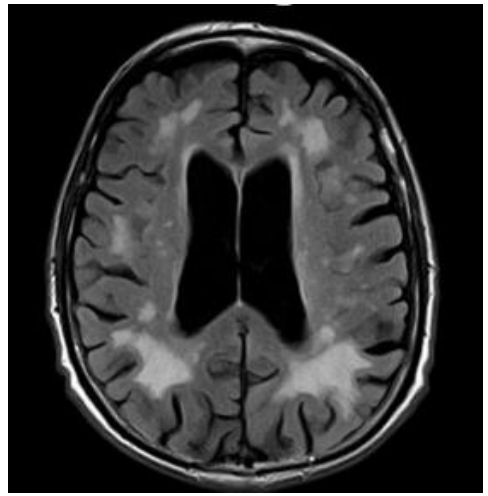
Small vessel disease:

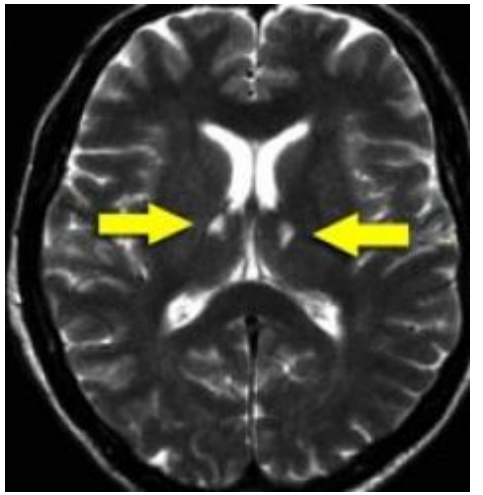
Either >25% of white matter involved

OR >=2 lacunar infarcts in basal ganglia/internal capsule

AND >=2 lacunar infarcts frontal WM

OR bilateral thalamic infarcts





Roman GC Neurology 1993

Vascular cognitive impairment (VCI)

VCI: contribution of vascular pathology to any severity of cognitive impairment, ranging from subjective cognitive decline and mild cognitive impairment to dementia

The key requirements for a diagnosis of VCI are:

(1) demonstration of a cognitive deficit by neuropsychological testing

(2) presence of cerebrovascular disease at imaging

VCI refers to all forms of cognitive deficits of vascular origin ranging from MCI to dementia. Diagnosis must be based on cognitive testing involving a minimum of 4 cognitive domains, including executive/attention, memory, language, and visuospatial functions.
Vascular dementia (VaD) requires a decline in cognitive function and a deficit in performance in ≥2 cognitive domains that are of sufficient severity to affect activities of daily living.
Vascular mild cognitive impairment (VaMCI) includes 4 subtypes: amnestic, amnestic plus other domains, nonamnestic single domain, and nonamnestic multiple domain; VaMCI should be based on the assumption of a decline in cognitive function. Activities of daily living may be normal or mildly impaired.
Probable: A diagnosis of probable VaD or VaMCI requires the following:
(1) Imaging evidence of cerebrovascular disease and (a) a clear temporal relationship between a vascular event (eg, stroke) and onset of cognitive deficits or (b) a clear relationship between the severity and pattern of cognitive impairment and the presence of diffuse subcortical vascular pathology;
(2) Absence of a history of gradually progressive cognitive deficits, suggesting the presence of neurodegenerative disease.
Possible: A diagnosis of possible VaD or VaMCI requires imaging evidence of cerebrovascular disease and should be made if there is no clear relationship between vascular disease and cognitive impairment, if the criteria for probable VaD or VaMCI are not fulfilled, if aphasia precludes proper cognitive assessment, or if there is a history of active cancer or psychiatric or metabolic disorders that may affect cognitive function.
Unstable VaMCI: subjects with probable of possible VaMCI whose symptoms revert to normal

Evaluation of different patterns of correlation between gray matter (GM) and WM microstructural changes in pure ADD, pure SVaD, and mixed dementia.

40 Pittsburgh compound B (PiB) positive ADD patients without WM hyperintensities (pure ADD)

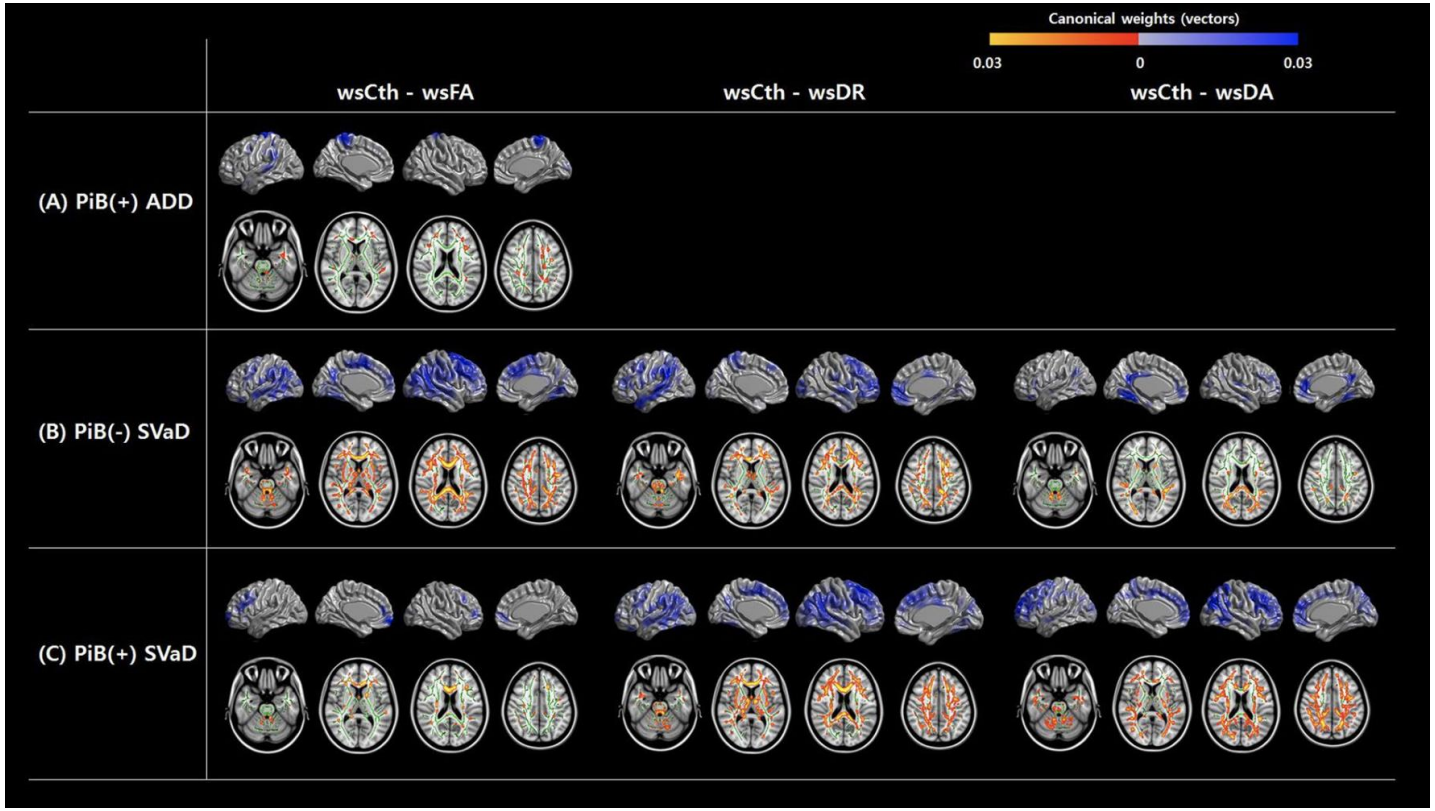
32 PiB negative SVaD patients (pure SVaD)

23 PiB positive SVaD patients (mixed dementia)

56 normal controls

WM microstructural integrity quantified by DWI using fractional anisotropy (FA), axial diffusivity (DA), and radial diffusivity (DR) value

Correlation between cortical thickness and white matter integrity



In the pure ADD group, disruption of WM integrity was minimal with lower DA in WM adjacent to the cortex

In pure SVaD and mixed dementia, there was extensive disruption of WM integrity with higher DR and overall higher DA, but lower DA in WM adjacent to the cortex

Cortical thinning in pure SVaD strongly correlated with changes in FA and DR, while cortical thinning in mixed dementia strongly correlated with changes in DR and DA

These findings suggest that the relationship between GM and WM degeneration differs according to the underlying pathobiology

ABSTRACT

Objective: To characterize brain network connectivity impairment in cerebral small-vessel disease (SVD) and its relationship with MRI disease markers and cognitive impairment.

Methods: A cross-sectional design applied graph-based efficiency analysis to deterministic diffusion tensor tractography data from 115 patients with lacunar infarction and leukoaraiosis and 50 healthy individuals. Structural connectivity was estimated between 90 cortical and subcortical brain regions and efficiency measures of resulting graphs were analyzed. Networks were compared between SVD and control groups, and associations between efficiency measures, conventional MRI disease markers, and cognitive function were tested.

Results: Brain diffusion tensor tractography network connectivity was significantly reduced in SVD: networks were less dense, connection weights were lower, and measures of network efficiency were significantly disrupted. The degree of brain network disruption was associated with MRI measures of disease severity and cognitive function. In multiple regression models controlling for confounding variables, associations with cognition were stronger for network measures than other MRI measures including conventional diffusion tensor imaging measures. A total mediation effect was observed for the association between fractional anisotropy and mean diffusivity measures and executive function and processing speed.

Conclusions: Brain network connectivity in SVD is disturbed, this disturbance is related to disease severity, and within a mediation framework fully or partly explains previously observed associations between MRI measures and SVD-related cognitive dysfunction. These cross-sectional results highlight the importance of network disruption in SVD and provide support for network measures as a disease marker in treatment studies. *Neurology*® 2014;83:304–311

The cumulative effect of small vessel disease lesions is reflected in structural brain networks of memory clinic patients

Rutger Heinen[a,1], Naomi Vlegels[a,*,1], Jeroen de Bresser[b,c], Alexander Leemans[d], Geert Jan Biessels[a], Yael D. Reijmer[a], On behalf of the Utrecht Vascular Cognitive Impairment study group

Methods: 173 patients from the memory clinic of the University Medical Center Utrecht underwent a 3 T brain MRI scan (including diffusion MRI sequences) and neuropsychological testing. MRI markers for SVD were rated and compiled in a previously developed total SVD score. Structural brain networks were reconstructed using fiber tractography followed by graph theoretical analysis. The relationship between total SVD burden score, global network efficiency and cognition was assessed using multiple linear regression analyses.

The cumulative effect of small vessel disease lesions is reflected in structural brain networks of memory clinic patients

Rutger Heinen[a,1], Naomi Vlegels[a,*,1], Jeroen de Bresser[b,c], Alexander Leemans[d], Geert Jan Biessels[a], Yael D. Reijmer[a], On behalf of the Utrecht Vascular Cognitive Impairment study group

Results: Each point increase on the SVD burden score was associated with 0.260 [−0.404 - -0.117] SD units decrease of global brain network efficiency ($p < .001$). Global network efficiency was associated with information processing speed (standardized $B = -0.210$, $p = .004$) and attention and executive functioning ($B = 0.164$, $p = .042$), and mediated the relationship between SVD burden and information processing speed ($p = .027$) but not with executive functioning ($p = .12$).

Conclusion: Global network efficiency is sensitive to the cumulative effect of multiple manifestations of SVD on brain connectivity. Global network efficiency may therefore serve as a useful marker for functionally relevant SVD-related brain injury in clinical trials.

Imaging biomarkers of SVD: new players

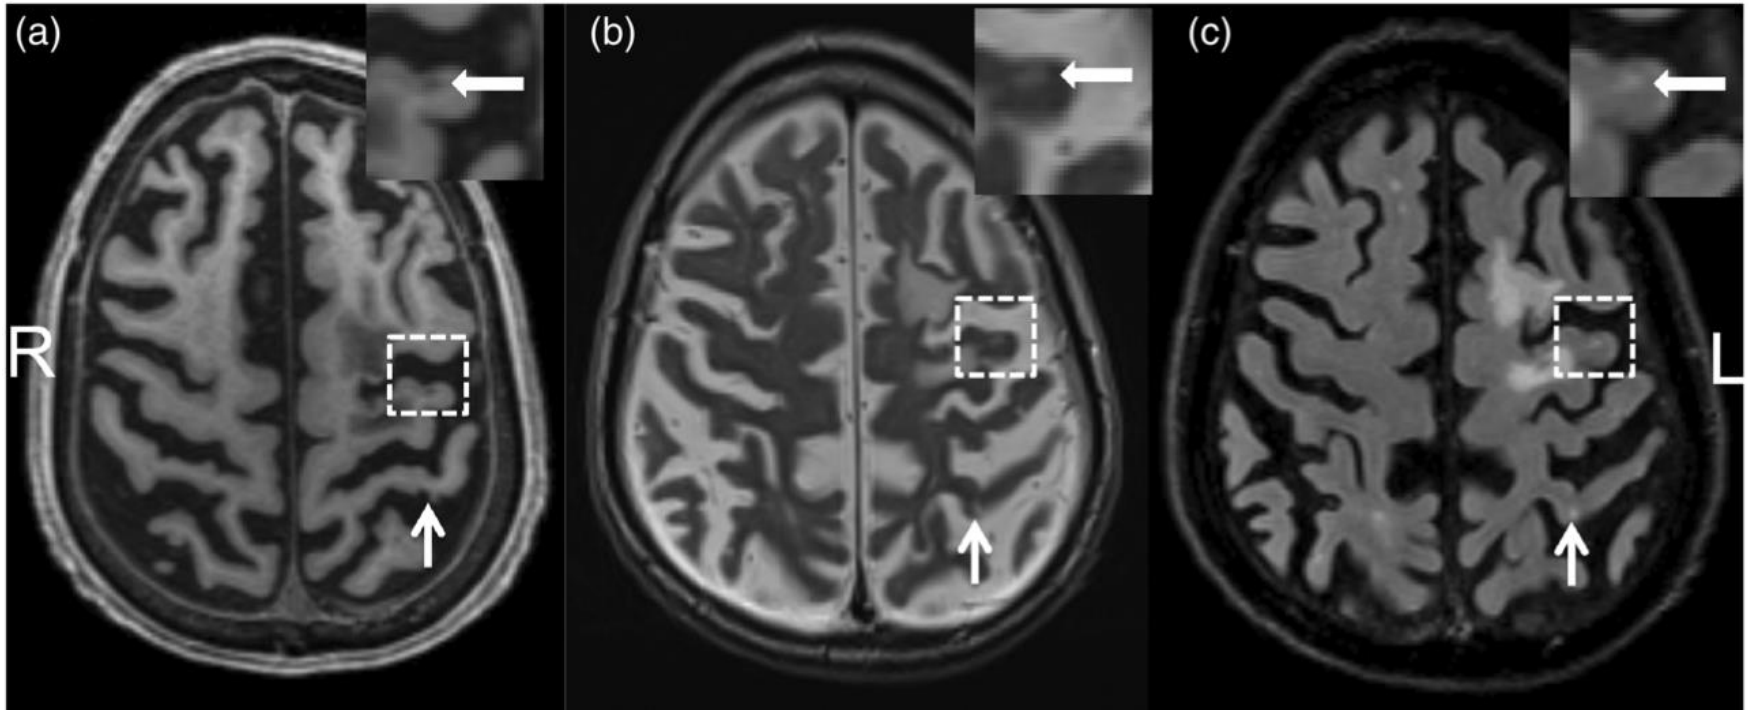
Cortical cerebral microinfarcts predict cognitive decline in memory clinic patients

Saima Hilal[1,2,3], Chuen Seng Tan[4], Susanne J van Veluw[5,6], Xin Xu[1,2], Henri Vrooman[7], Boon Y Tan[8], Narayanaswamy Venketasubramanian[9], Geert J Biessels[6] and Christopher Chen[1,2,10]



313 patients with baseline 3T MRI scans

At least two neuropsychological assessments

Cortical CMIs graded on baseline MRI

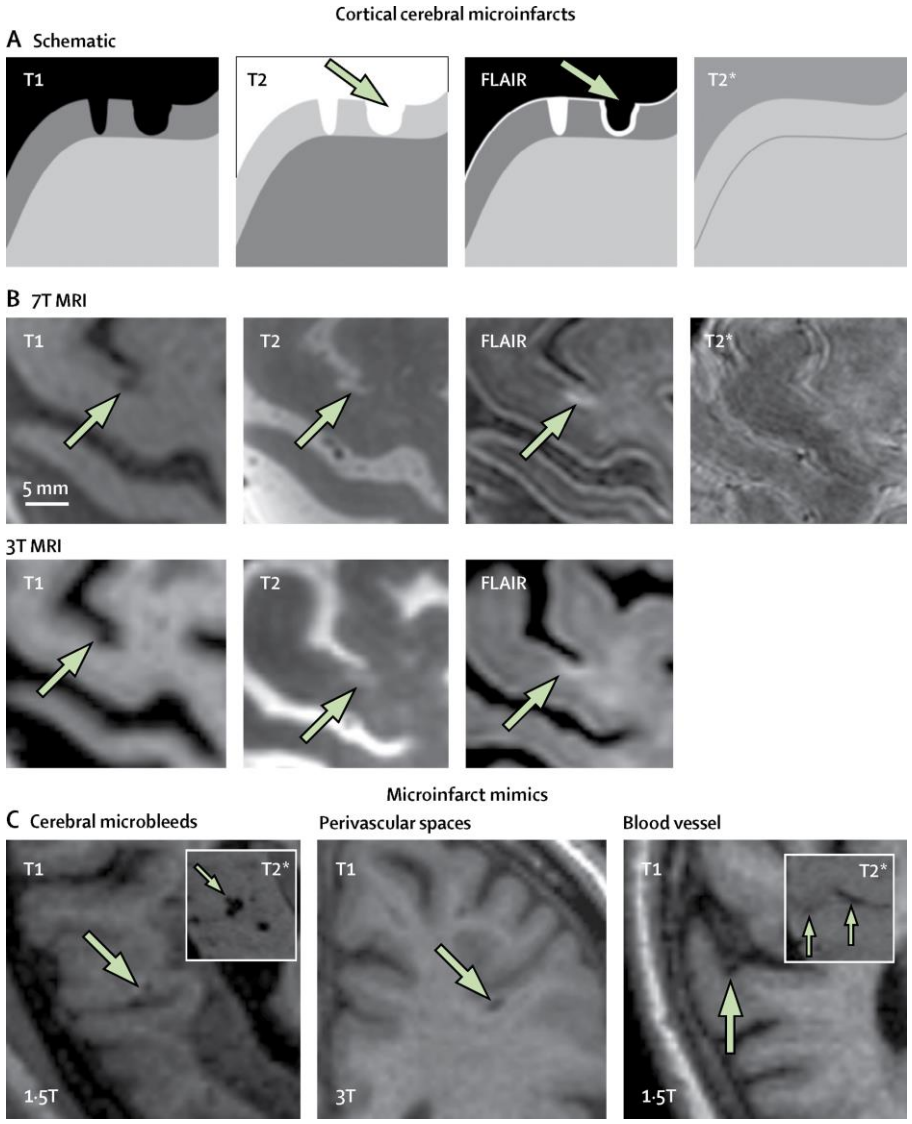
The Montreal Cognitive Assessment (MoCA) and a neuropsychological battery to assess cognition

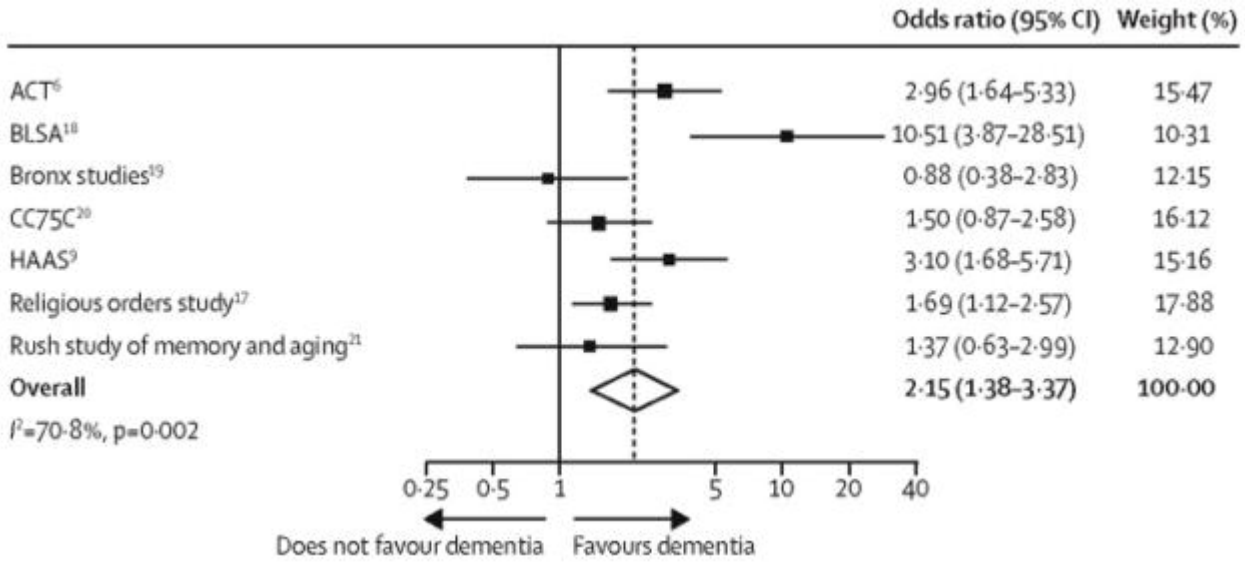
Patients with increased cortical CMIs showed greater decline in MoCA and global cognition per year

Patients with > 2 cortical CMIs decline on average by 2 scores on MoCA and 0.5 on global cognition at year two

Furthermore, cortical CMIs at baseline were associated with accelerated decline in memory and language domains

Imaging biomarkers of SVD: new players



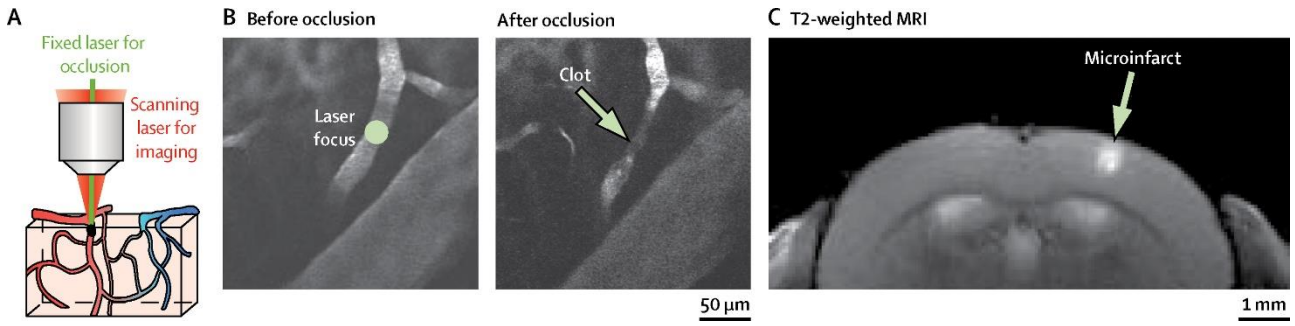


Pooled Odds of Dementia in Persons with cortical microinfarcts

Causes of cerebral microinfarcts (CM)

CM have multiple underlying causes, which can coexist in a single patient:

1) Cerebral small vessel disease (eg, cerebral amyloid angiopathy, arteriolosclerosis)
2) Microemboli
3) Hypoperfusion



Cerebral microinfarcts have been successfully modelled in the brains of rodents by occluding penetrating arterioles

Penetrating arterioles are a key locus for occlusion, because unlike the interconnected pial and capillary systems, blood flow through a penetrating arteriole cannot be efficiently re-routed around a localised clot

Cortical Microinfarcts and White Matter Connectivity in Memory Clinic Patients

CMI, Cerebral microinfarct; FA, Fractional anisotropy-weighted WM connectivity; MD, Mean diffusivity-weighted WM connectivity. Lower FA and higher MD indicated impaired WM connectivity.

[a]MD values $\times 10^{-3}$ mm^2/s.

Model 1: Covariates age and sex (degrees of freedom = 160).

Model 2: Covariates sex, age, WMH Fazekas grade 3, presence of lacunar and non-lacunar infarct (degrees of freedom = 157).

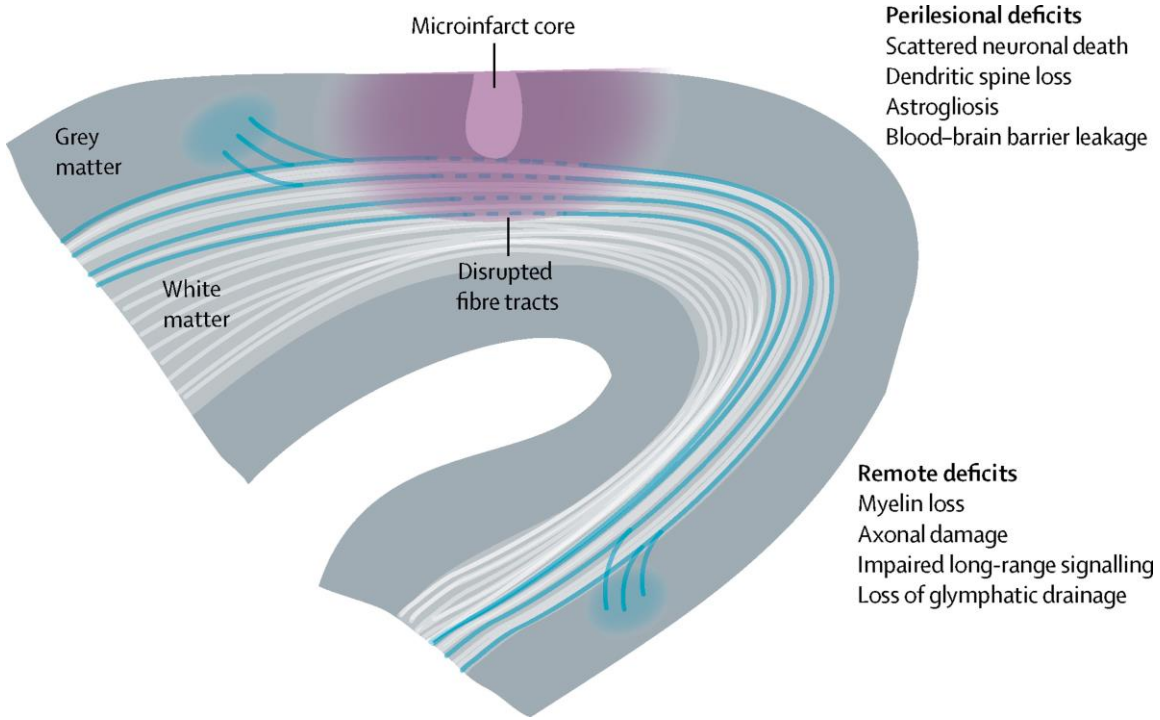
no evidence that the actual presence of cortical CMIs was related to disruption of WM connections to either the high CMI burden regions or within the whole brain.

Effects of cerebral microinfarcts (CM)

CM can have physio-pathological effects that extend beyond the non-viable core observed by MRI or in neuropathological studies

Neuronal dysfunction might involve diaschisis, whereby death of neurons within the CM core disables the cortical and subcortical circuits to which they were previously integrated

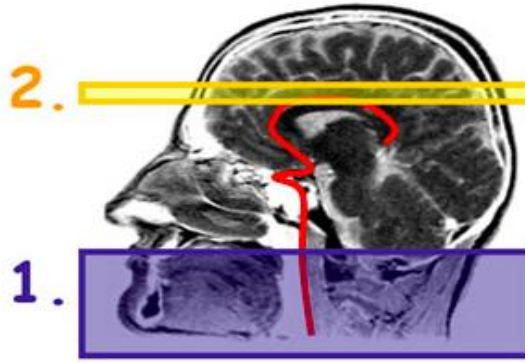
CM affecting white matter tracts are likely to disrupt communication between brain regions by damaging axonal structures

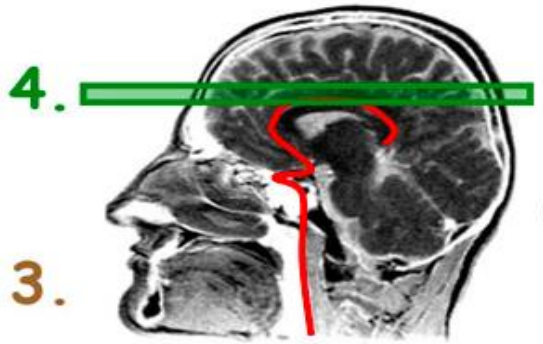


Future directions

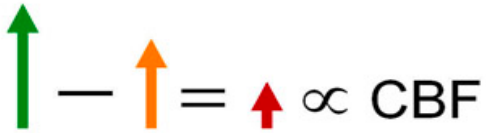
Imaging di perfusione - ASL

1. Tag inflowing arterial blood by magnetic inversion
2. Acquire the **Tag Image**





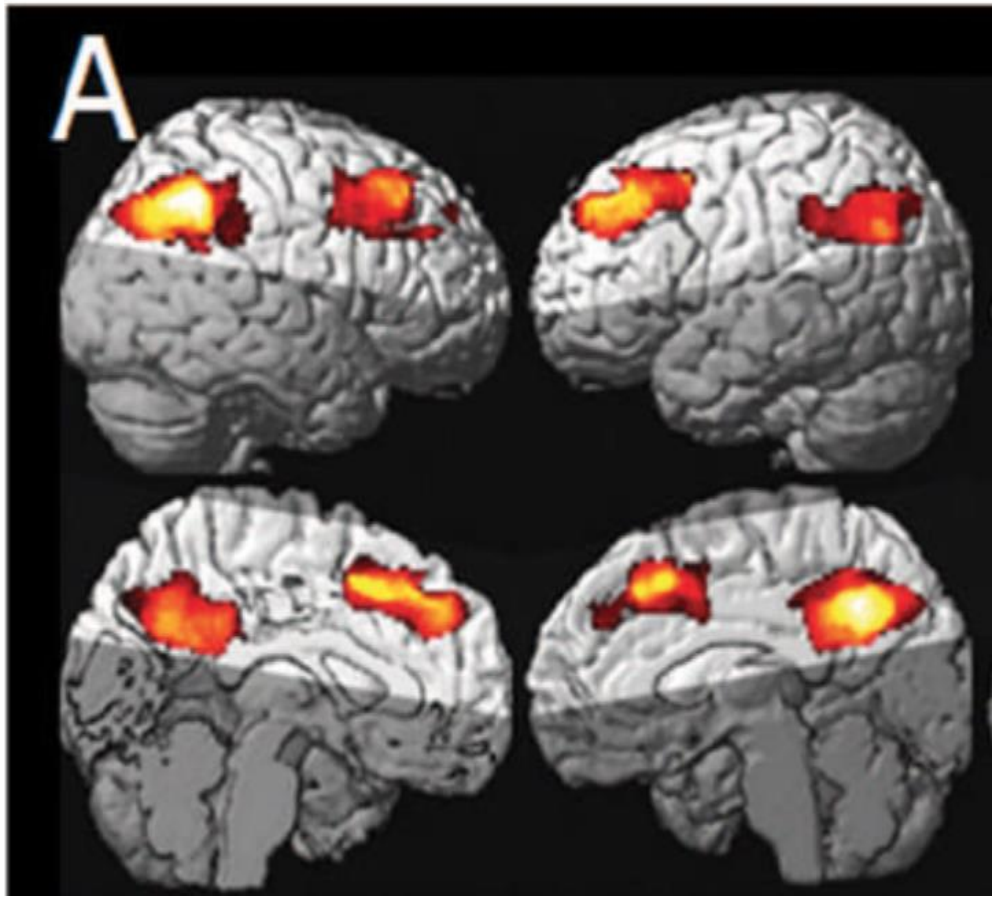
3. Repeat experiment without tag
4. Acquire the **Control Image**
5. Subtract: **Control Image** - **Tag Image**



The **Difference** in magnetization between control and tag conditions is proportional to regional cerebral blood flow.

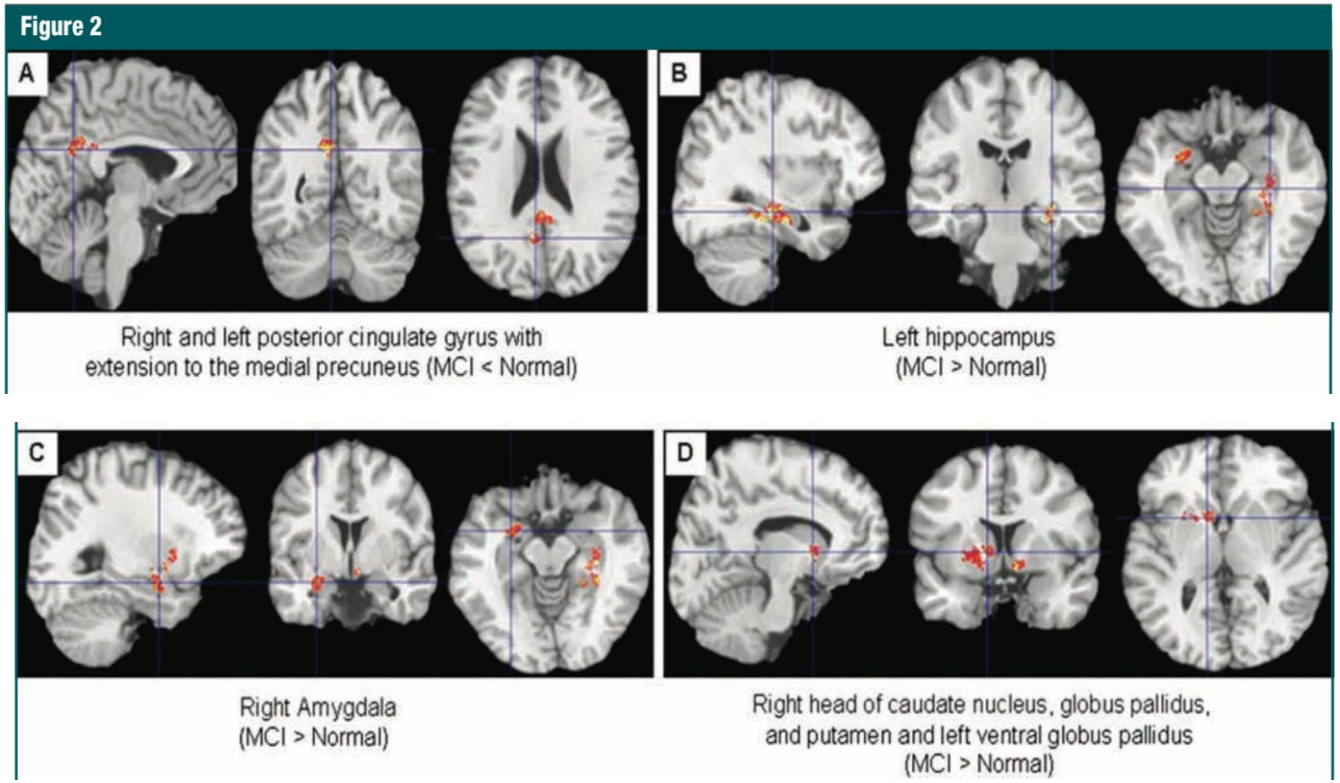
- L'iperperfusione puo' riflettere un aumento di attivita' di natura compensatoria in una popolazione neuronale minimamente coinvolta dal processo neurodegenerativo
- L'ipoperfusione puo' segnalare una riduzione dell'attivita' neuronale prima che le alterazioni strutturali siano diventate evidenti

Imaging di perfusione - AD



Johnson et al., Radiology 2005

- In pazienti AD, il pattern di ipoperfusione comprende le aree parietali e frontali bilateralmente.



Dai et al., Radiology 2009

- L'imaging di perfusione e' in grado di mostrare aree di aumentata attivita' neuronale in pazienti MCI.

Imaging di perfusione - FTD
