However..

Use in **hybrid research/clinical context** + urgent need
lead to use before regulators approval

IL CERVELLO CHE CAMBIA 7

Sabato 11 novembre 2017

Genova, Aula Magna Clinica Neurologica

However..

bad biomarker \approx bad drug

e.g., problems posed by PSA for prostate cancer.

Inconsistent prescription (depending on availability, physician's familiarity with the exam, waiting list...)

Inconsistent refund

Suboptimal use of resources

Drugs to be prescribed based on biomarker-based diagnosis

Proposal: the Geneva Biomarker Roadmap Initiative

How to boost development → regulation → rational use?

Define a systematic methodological framework for
biomarker validation

Borrow from **oncology** (Pepe et al., 2001)

COMMENTARY

Phases of Biomarker Development for Early Detection of Cancer

Margaret Sullivan Pepe, Ruth Etzioni, Ziding Feng, John D. Potter, Mary Lou Thompson, Mark Thornquist, Marcy Winget, Yutaka Yasui

1) INTRODUCTION

Recent developments in such areas of research as gene-expression microarrays, proteomics, and immunology offer new approaches to cancer screening (1). The surge in research to develop cancer-screening biomarkers prompted the establishment of the Early Detection Research Network (EDRN) by the National Cancer Institute (2). The purpose of the EDRN is to coordinate research among biomarker-development laboratories, biomarker-validation laboratories, clinical repositories, and population-screening programs. By coordination of research efforts, the hope is to facilitate collaboration and to promote efficiency and rigor in research.

noninvasively. Biomarkers, however, may be more complicated and/or indirect, involving, for example, measures of immune response to a developing tumor, hormonal changes induced by a tumor, or mass spectrometry profiles of serum protein. In this commentary, we use the term “biomarker” for cancer detection in a broad sense.

Cancer is a diverse disease, and it is unlikely that a single biomarker will detect all cancer of a particular organ with high specificity and sensitivity. Indeed, biomarkers, such as prostate-specific antigen (PSA), that purport to have high sensitivity tend to have low specificity because they do not detect cancer *per se* but rather a more general process. We note that maintaining high specificity (low false-positive rates) is a very high priority for population screening. Even a small false-positive rate translates

The oncology framework- Phases I-II

Phase 1	
Preclinical Exploratory Studies	To identify and prioritize leads for potentially useful biomarkers.
Phase 2	
Clinical Assay Development for Clinical Disease	To estimate the true and false positive rate or ROC curve and assess its ability to distinguish subjects with and without the disease .
	To optimize procedures for performing the assay and to assess the reproducibility of the assay within and between laboratories.
	To determine the relationship between biomarker measurements made on tumor tissue (phase 1) and the biomarker measurements made on the noninvasive clinical specimen (phase 2).
	To assess factors (e.g. sex, age, etc.), associated with biomarker status or level in control subjects . If such factors affect the biomarker, thresholds for screen positivity may need to be defined separately for screening subpopulations to keep the FPR at a low level for each.
	To assess factors associated with biomarker status or level in cancer case subjects —in particular, disease characteristics such as stage, histology, grade and prognosis.

The oncology framework- Phase III

Phase 3	
Retrospective Longitudinal Repository Studies	To evaluate, as a function of time before clinical diagnosis, the capacity of the biomarker to detect preclinical disease .
	To define criteria for a positive screening test in preparation for phase 4.
	To explore the impact of covariates on the discriminatory abilities of the biomarker before clinical diagnosis.
	To compare markers with a view to selecting those that are most promising.
	To develop algorithms for screen positivity based on combinations of markers .
	To determine a screening interval for phase 4 if repeated testing is of interest.

The oncology framework- Phase IV

Phase 4	
Prospective Screening Studies	to determine the operating characteristics of the biomarker-based screening test in a relevant population by determining the detection rate and the false referral rate.
	To describe the characteristics of tumors detected by the screening test—in particular, with regard to the potential benefit incurred by early detection.
	To assess the practical feasibility of implementing the screening program and compliance of test-positive subjects with work-up and treatment recommendations.
	To make preliminary assessments of the effects of screening on costs and mortality associated with cancer .
	To monitor tumors occurring clinically but not detected by the screening protocol

The oncology framework- Phase V

Phase 5	
Cancer Control Studies	to estimate the reductions in cancer mortality afforded by the screening test
	To obtain information about the costs of screening and treatment and the cost per life saved .
	To evaluate compliance with screening and work-up in a diverse range of settings .
	To compare different screening protocols and/or to compare different approaches to treating screen-detected subjects in regard to effects on mortality and costs.

Context of use

Purpose

Determine whether clinical diagnosed MCI in patients accessing memory clinics is due to AD

Nature of the disease

Insidious onset due to slowly progressive, well-characterized neurodegenerative processes that begin up to many years before the overt clinical onset of AD.

Population

the MCI population that is non-proactively screened but who autonomously refers or is referred to a memory clinic or other third-level specialist health service (→ NO screening)

Neuropsychology (Gatekeeper) – Validation Status

Development of Free and Cued Wordlist Recall adapted from the framework of Pepe et al. 2001

Phase 1: Rational for the use of Free and Cued Wordlist Recall		Phase 2: Discrimination ability of Free and Cued Wordlist Recall		Phase 3: Detection ability in early phase		Phase 4: Free and Cued Wordlist Recall accuracy in representative MCI patients		Phase 5: Quantify impact of Free and Cued Wordlist Recall-based diagnosis on relevant outcomes	
Primary aim		Primary aim	Secondary aims	Primary aims	Secondary aims	Primary aim	Secondary aims	Primary aim	Secondary aims
Potential leads		Identify discrimination accuracy AD/HC	Assay definition	Assess capacity of earliest (MCI) detection	Impact of covariates	Assess true/false referral rate in Free and Cued Wordlist Recall diagnosed patients	Detect predictive features	Estimate impact on morbidity & disability	Cost/ benefit quantification
			Ante mortem/ autopsy		Compare markers		Practical feasibility		Compliance in different settings
			Covariates in HC	Criteria for positivity	Combine markers		Estimate impact & costs		Compare different protocols
			Covariates in AD		Determine testing Interval		Monitor false negatives		

Achievement		
Full	Partial	
Preliminary	Not achieved	Not applicable

Neuropsychology (Gatekeeper) - Research Priorities

Comparing different neuropsychological tests assessing memory function for sensitivity, specificity, positive and negative predictive values

Defining a **consensus delayed recall test with multilingual versions and the relative normative populations**

Define a consensus algorithm based on neuropsychological tests to access biomarker assessment

Define a consensus neuropsychological test battery required to **support a diagnosis of “atypical”** (non-memory) AD presentations

Lancet Neurol, 2017;16:661-676.

Medial Temporal Atrophy – Validation Status

Development of MTA adapted from the framework of Pepe et al. 2001

Phase 1: Rational for the use of MTA	Phase 2: Discrimination ability of MTA		Phase 3: Detection ability in early phase		Phase 4: MTA accuracy in representative MCI patients		Phase 5: Quantify impact of MTA-based diagnosis on relevant outcomes	
Primary aim	Primary aim	Secondary aims	Primary aims	Secondary aims	Primary aim	Secondary aims	Primary aim	Secondary aims
Potential leads	Identify discrimination accuracy AD/HC	Assay definition Ante mortem/autopsy	Assess capacity of earliest (MCI) detection	Impact of covariates Compare markers	Assess true/false referral rate in MTA diagnosed patients	Detect predictive features Practical feasibility Estimate impact & costs Monitor false negatives	Estimate impact on morbidity & disability	Cost/ benefit quantification Compliance in different settings Compare different protocols
<div>Achievement</div> <div> <div>Full</div> <div>Partial</div> <div>Preliminary</div> <div>Not achieved</div> <div>Not applicable</div> </div>		Covariates in HC Covariates in AD	Criteria for positivity	Determine testing Interval				

Medial Temporal Atrophy – Research Priorities

Phase II Clinical Assay Development for Clinical Disease

SA1 Define a **standard validation procedure for automated segmentation algorithms** based on the harmonized manual segmentation protocol

Assess reproducibility between different algorithms

Phase III Prospective Longitudinal Repository Studies

PA1 Assess accuracy of prediction of MCI progression to AD in clinical samples with adequate follow-up

PA2 Define the **threshold** for hippocampal atrophy taking into account the effect of covariates

SA1 Explore the impact of covariates on the discriminatory abilities of hippocampal volumetry in detecting MCI due to AD

Lancet Neurol, 2017;16:661-676.

Amyloid Imaging - Validation Status

Development of **amyloid PET** adapted from the framework of Pepe et al. 2001

Phase 1: Rational for the use of amyloid PET	Phase 2: Discrimination ability of amyloid PET		Phase 3: Detection ability in early phase		Phase 4: Amyloid PET accuracy in representative MCI patients		Phase 5: Quantify impact of amyloid PET-based diagnosis on relevant outcomes	
Primary aim	Primary aim	Secondary aims	Primary aims	Secondary aims	Primary aim	Secondary aims	Primary aim	Secondary aims
Potential leads	Identify discrimination accuracy AD/HC	Assay definition Ante mortem/autopsy	Assess capacity of earliest (MCI) detection	Impact of covariates Compare markers	Assess true/false referral rate in amyloid PET diagnosed patients	Detect predictive features Practical feasibility Estimate impact & costs	Estimate impact on morbidity & disability	Cost/ benefit quantification Compliance in different settings Compare different protocols
<div>Achievement</div> <div> <div>Full</div> <div>Partial</div> <div>Prelim-inary</div> <div>Not achieved</div> </div>		Covariates in HC Covariates in AD	Criteria for positivity	Combine markers Determine testing interval		Monitor false negatives		

Amyloid Imaging – Research Priorities

Phase II Clinical Assay Development for Clinical Disease

SA1 **Assess on the same population comparability and reproducibility of ligands, operating procedures, and readout methods.**

SA3 Assess the impact of covariates (gender, education, levels of cognitive activity) on ligands uptake and define whether and how they should affect the definition of positivity. SA4 Assess the effect of disease characteristics (stage, genotype, disease onset, clinical manifestation) and other covariates in patients on levels of uptake, to quantify the informative value of amyloid imaging in patients

Phase III Prospective Longitudinal Repository Studies

PA1 Discrimination ability of MCI due to AD may provide more stable results if re-run after definition of one standard procedure

PA2 Progress the definition of positivity mainly by **standardizing the reading criteria** SA1 Collect evidence on the impact of covariates on the discriminatory abilities of the biomarker

SA2 Compare the predictive performance of amyloid imaging versus other biomarkers (particularly CSF A β 42, assessed with the new standard)

SA3 Develop sensitive **algorithms** for positivity based on combinations of amyloid imaging and other markers

SA4 Investigate the meaning of intermediate levels of uptake (quantitative assessment) or dubious cases (visual assessment) and define whether **repeated testing** may be useful, at which time interval, and for which patients

Cerebrospinal Fluid Abeta & Tau – Validation Status

Development of **CSF biomarkers** adapted from the framework of Pepe et al. 2001

Phase 1: Rational for the use of CSF biomarkers		Phase 2: Discrimination ability of CSF biomarkers		Phase 3: Detection ability in early phase		Phase 4: CSF biomarkers accuracy in representative MCI patients		Phase 5: Quantify impact of CSF biomarkers-based diagnosis on relevant outcomes			
Primary aim		Primary aim	Secondary aims	Primary aims	Secondary aims	Primary aim	Secondary ais	Primary aim	Secondary aims		
Potential leads	Identify discrimination accuracy AD/HC	Assay definition	Assess capacity of earliest (MCI) detection	Impact of covariates	Assess true/false referral rate in CSF biomarkers diagnosed patients	Detect predictive features	Estimate impact on morbidity & disability	Cost/ benefit quantification			
		Ante mortem/ autopsy		Compare markers		Practical feasibility		Compliance in different settings			
		Covariates in HC		Combine markers		Estimate impact & costs		Compare different protocols			
<div>Achievement</div> <table><tr><td>Full</td><td>Partial</td></tr><tr><td>Preliminary</td><td>Not achieved</td></tr></table>		Full	Partial	Preliminary	Not achieved	Covariates in AD	Criteria for positivity	Determine testing Interval		Monitor false negatives	
		Full	Partial								
Preliminary	Not achieved										

Cerebrospinal Fluid Abeta & Tau – Research Priorities

Phase II Clinical Assay Development for Clinical Disease

SA1 Develop&implement optimized protocol for standardized pre-analytical handling of CSF samples. Validate **novel fully automated immunoassays**, using Certified Reference Materials (CRM).

SA3 Determine the effects of non-AD brain pathologies on the CSF levels of different variants of A β and tau.

SA4 Assess the effects of disease characteristics (stage, genotype, disease onset, clinical manifestation) and other covariates on the levels of CSF biomarkers.

Phase III Prospective Longitudinal Repository Studies

PA2 Define cut off values for all CSF biomarkers (or CSF biomarker ratios) using the optimized protocol for standardized pre-analytical handling of CSF samples. This needs to be done for each new fully automated immunoassay using a suitable reference (e.g. pathology or amyloid PET).

SA2 Determine the optimal combination of different CSF biomarkers for detection of MCI due to AD when using the optimized protocol for standardized pre-analytical handling of CSF samples in combination with novel fully automated immunoassays and Certified Reference Materials (CRM).

SA3 Develop optimal algorithms combining CSF biomarkers with other measures, including MRI and cognitive tests.

SA4 Determine the intra-individual changes of CSF biomarkers over time during prodromal stages of AD when using the optimized protocol for standardized pre-analytical handling of CSF samples in combination with novel fully automated immunoassays and Certified Reference Materials (CRM).

Lancet Neurol, 2017;16:661-676.

FDG-PET – Validation Status

Development of **18F-FDGPET** adapted from the framework of Pepe et al. 2001

Phase 1: Rational for the use of 18F-FDGPET		Phase 2: Discrimination ability of 18F-FDGPET		Phase 3: Detection ability in early phase		Phase 4: 18F-FDGPET accuracy in representative MCI patients		Phase 5: Quantify impact of 18F-FDGPET-based diagnosis on relevant outcomes	
Primary aim		Primary aim	Secondary aims	Primary aims	Secondary aims	Primary aim	Secondary ais	Primary aim	Secondary aims
Potential leads		Identify discrimination accuracy AD/HC	Assay definition	Assess capacity of earliest (MCI) detection	Impact of covariates	Assess true/false referral rate in 18F-FDGPET diagnosed patients	Detect predictive features	Estimate impact on morbidity & disability	Cost/ benefit quantification
			Ante mortem/ autopsy		Compare markers		Practical feasibility		Compliance in different settings
			Covariates in HC		Combine markers		Estimate impact & costs		Compare different protocols
			Covariates in AD		Determine testing Interval		Monitor false negatives		
<div>Achievement<div><div>Full</div><div>Partial</div><div>Preliminary</div><div>Not achieved</div></div></div>									

FDG-PET – Research Priorities

Phase II Clinical Assay Development for Clinical Disease

SA4 Assess the **effect of covariates** and disease characteristics (stage, onset of disease, clinical presentation, reserve capacity, comorbidities, genotype) on levels and distribution of cerebral glucose hypometabolism and on normality thresholds.

Phase III Prospective Longitudinal Repository Studies

PA1 Assessment of the accuracy of FDG-PET in prodromal AD detection may need to be re-assessed after completion of SA4, to investigate possibly better performance

PA2 **Harmonize reading criteria and determine a standard threshold for hypometabolism**; validate the reading procedures for reproducibility

Lancet Neurol, 2017;16:661-676.

Biomarkers for LBD – Validation Status

Development of ¹²³I-ioflupane SPECT adapted from the framework of Pepe et al. 2001

Phase 1: Rational for the use of 123I-ioflupane SPECT		Phase 2: Discrimination ability of 123I-ioflupane SPECT		Phase 3: Detection ability in early phase		Phase 4: 123I-ioflupane SPECT accuracy in representative MCI patients		Phase 5: Quantify impact of 123I-ioflupane SPECT-based diagnosis on relevant outcomes	
Primary aim		Primary aim	Secondary aims	Primary aims	Secondary aims	Primary aim	Secondary aims	Primary aim	Secondary aims
Potential leads		Identify discrimination accuracy AD/HC	Assay definition	Assess capacity of earliest (MCI) detection	Impact of covariates	Assess true/false referral rate in 123I-ioflupane SPECT diagnosed patients	Detect predictive features	Estimate impact on morbidity & disability	Cost/ benefit quantification
			Ante mortem/ autopsy		Compare markers		Practical feasibility		Compliance in different settings
			Covariates in HC		Combine markers		Estimate impact & costs		Compare different protocols
<div><div>Achievement</div><div><div>Full</div><div>Partial</div></div><div><div>Preliminary</div><div>Not achieved</div><div>Not applicable</div></div></div>			Covariates in AD	Criteria for positivity	Determine testing Interval		Monitor false negatives		

Biomarkers for LBD – Validation Status

Development of **123I-MIBG SPECT** adapted from the framework of Pepe et al. 2001

Phase 1: Rational for the use of 123I-MIBG SPECT		Phase 2: Discrimination ability of 123I-MIBG SPECT		Phase 3: Detection ability in early phase		Phase 4: 123I-MIBG SPECT accuracy in representative MCI patients		Phase 5: Quantify impact of 123I-MIBG SPECT-based diagnosis on relevant outcomes	
Primary aim	Primary aim	Secondary aims	Primary aims	Secondary aims	Primary aim	Secondary aims	Primary aim	Secondary aims	
Potential leads	Identify discrimination accuracy AD/HC	Assay definition	Assess capacity of earliest (MCI) detection	Impact of covariates	Assess true/false referral rate in 123I-MIBG SPECT diagnosed patients	Detect predictive features	Estimate impact on morbidity & disability	Cost/ benefit quantification	
		Ante mortem/ autopsy		Compare markers		Practical feasibility		Compliance in different settings	
		Covariates in HC	Criteria for positivity	Combine markers		Estimate impact & costs		Compare different protocols	
<div>Achievement</div> <div><div>Full</div><div>Partial</div></div> <div><div>Preliminary</div><div>Not achieved</div><div>Not applicable</div></div>		Covariates in AD		Determine testing Interval	Monitor false negatives				

Biomarkers for LBD – Research Priorities

Phase II Clinical Assay Development for Clinical Disease

SA2 Investigate the relationship between DaT SPECT and the degeneration of the nigrostriatal dopaminergic system postmortem in the same sample.

Phase III Prospective Longitudinal Repository Studies

PA1 Evaluate the capacity of DaT SPECT to **discriminate DLB at the MCI stage**, in samples with availability of reference standard (at least clinical diagnosis at follow up)

PA2 Define criteria for positivity, based on the discrimination ability demonstrated in PA1

SA1 Explore the impact of covariates on the discriminatory abilities of the biomarker in MCI samples, and versus a reference standard (at least diagnosis at follow up)

SA2 Compare the performance of DaT SPECT with AD biomarkers in MCI samples

SA3 Develop an **algorithm** entering DaT SPECT in the diagnostic work-up in optimal combination with other biomarkers

Lancet Neurol, 2017;16:661-676.

Discussion

Current state of development and validation of biomarkers for the early and differential diagnosis of Alzheimer's disease. PA: primary aim. SA: secondary aim. Green: fully achieved; yellow: partly achieved; orange: preliminary evidence; red: not achieved; white: not applicable.

Biomarker	Phase I	Phase II					Phase III							Phase IV					Phase V
	Pilot Studies	Clinical Assay Development for Clinical Disease					Retrospective Longitudinal Repository Studies							Prospective Diagnostic Studies					Disease Control Studies
	PA	PA	SA1	SA2	SA3	SA4	PA1	PA2	SA1	SA2	SA3	SA4	PA	SA1	SA2	SA3	SA4		
MR medial temporal atrophy																			
¹⁸ F-fluorodeoxy-glucose PET																			
¹¹ C-PIB, ¹⁸ F amyloid ligands PET																			
CSF (Aβ42, tau, p-tau)																			
¹²³ I-ioflupane SPECT																			
¹²³ I-MIBG SPECT																			

Achievement  Full  Partial  Preliminary  Not Achieved

Discussion

- Gaps → research priorities identified
- Biomarkers should be used in qualified memory clinics
- Need of clinical guidelines: available for SINGLE biomarker
- Patients should be informed about the “research” use of biomarkers
- Roadmap may be used by researchers and funders
